In this lab, I used four key Python libraries - OGR, Shapely, Fiona, and GeoPandas - to examine geographic data in depth. The investigation began with the creation of vector geometries like polygons using the OGR package. By linking together separate points, I illustrated how to define points and form polygons. In addition, I demonstrated how to read and write vector data as well as change vector geometries. I also demonstrated how to perform fundamental geometric operations such as calculating areas, centroids, and borders, as well as searching for points within a polygon. The tutorial then moved on to using Shapely and Fiona, both important library, to generate various geometries such as polygons, points, and lines. Shapely makes it easy to view geometries by simplifying the plotting process. Fiona is used for reading and interacting with shapefile. Then, it explains how to explore the data's characteristics and geometry. Following that, I learned to process more complex geospatial activities, such as spatial joins, choropleth map construction, and data inspection, using GeoPandas. These activities necessitated data reading and cleansing, as well as geographical operations to count and show wildfire occurrences by state.

Throughout the analysis, data inspection played a pivotal role in ensuring data quality and identifying missing or erroneous values. The guidance provides the techniques of how to check for missing values and empty fields in the dataset, emphasizing the importance of data quality for accurate analysis and visualization. This data analysis highlighted the versatility of these Python libraries for geospatial tasks, enabling users to handle geospatial data effectively from start to finish.
